

CFTRc Seminar Series

Dr. Caroline Wagner

Assistant Professor McGill University, Department of Bioengineering

Accounting for mucin biophysics in models of disease transmission

Numerous aspects of disease progression and transmission are intimately relateddst ibiophysical processes, including an important role for mucosal barriers. In this talk, I will describe tbjects in this area. Firstly, in terms of host and cellular susceptibility, we explore the physicochemical properties of mucus through rheological modeling as well as the development of diagnostics. Next, I will describe preliminary work in establishing the role of mucosalivary droplets in the viability of pathogens at the point of transmission, once emitted froin fectious hosts. The interaction of these processes with climate will also be considered. Finally, I'll describe our work studying pathogen transport in mucin gels, with the goal of improving our understanding of the initial stages of host infection, and temporal pathogen kinetics. Overall, the host mucin biophysical environment plays an important role in disease progression and transmission, and should be carefully considered in the context of ptipelævel disease models as well as the de2,9 (h) 275 (20) 260
